

Django Notes: Understanding {'form': form} in Views

1. Context Dictionary in Django

- In Django, when you do:

```
return render(request, 'core/signup.html', {'form': form})
```

- The third argument is called the context dictionary.
- It's data you want to send from your view (Python code) to your template (HTML page).

2. What is {'form': form}?

- It's a dictionary in Python:

Key = 'form' (a string)

Value = form (the SignUpForm object we created earlier)

- So {'form': form} means:

In the template, you can access the form object using the variable name form.

3. Why we need it?

- Without passing context, the template wouldn't know what data to display.
- Example:

```
form = SignUpForm()
```

```
return render(request, 'core/signup.html', {'form': form})
```

- Now in signup.html you can do:

```
{% csrf_token %}
```

```
{{ form.as_p }}
```

Sign Up

- Here, {{ form.as_p }} uses the form variable (passed in context).
- If you didn't pass {'form': form}, Django would raise an error because the template wouldn't know what form is.

4. Summary

- {'form': form} is a context dictionary.
- It lets us send Python objects (like a form, query results, or variables) to our HTML templates.
- The template can then display or process that data using Django Template Language ({{ }}).
